William R. More
Marine Biologist

Project No. MF-R-6 Date September 29, 1965

Project Name: Analysis of Populations of Sports and Commercial Fin-Fish and of Factors Which Affect these Populations in the Coastal Bays of Texas.

Period Covered: January 1, 1964 to December 31, 1964 Job No. 12

Hydrographic and Meteorological Study of the Galveston Bay System

Abstract: Hydrographic data obtained in the field and climatological data taken from publications are presented in this report.

Salinities varied little from 1963 readings, but were higher than 1962 figures.

Trinity River discharge was 56 per cent less than that recorded in 1963.

Above average water and air temperatures occurred during November and December.

Objectives: To gather information on the hydrography and meteorology of Galveston Bay and to present this information in a report that will be convenient for use in this project and other projects.

Procedure: Water samples were taken monthly at 48 stations distributed throughout the Galveston Bay system (Figure 1). Water temperature and pertinent meteorological and physical data were recorded at each station. Salinities were determined by the Mohr titration method.

Supplementary data on salinities and water temperatures were obtained from the Bureau of Commercial Fisheries Biological Laboratory at Galveston, Texas.

Information on air temperatures, wind, and precipitation was taken from "Climatological Data, Texas", while river discharge data was obtained from the Water Resources Division of the U. S. Department of Interior, Geological Survey Branch.

Findings and

Discussion: Monthly salinity determinations of 48 stations sampled during 1964 are given in Table 1. Salinity patterns were similar to those recorded in 1963 and slightly higher than 1962 recordings (Figure 2). The greatest variation occurred in upper Galveston Bay, Trinity Bay, and East Bay which are under the influence of river discharge and drainage from rice fields. A reverse correlation between river discharge and salinity was apparent in these areas (Figures 2 and 3). Increased salinity in the fall was mainly attributed to high tides resulting from strong southeasterly winds and a drop in river discharge after June 1963 (Figure 3).

In 1964 the lowest discharge on the Trinity River (1.1 million acre-feet) since 1956 was recorded. Figure 4 shows river discharge of the Trinity River at Romayor, Texas for the period 1951 - 1964. River discharge was above average during 1957, 1958 and 1961. All other years received less than 5 million acre-feet of water per year.

Precipitation was slightly higher in 1964 than in 1962 and 1963, but did not approach the high levels of 1961 (Figure 5). Approximately 50 per cent of the total 1964 rainfall (38.9 inches) fell during July, August, and December following a somewhat dry spring.

No fish kills due to low temperatures were observed. Unusually warm air temperatures during November and December were recorded at the Galveston airport (Table 3). Water temperature data recorded at the Galveston Laboratory of the U. S. Bureau of Commercial Fisheries indicated above average water temperatures during this period. Water temperatures recorded at hydrographic stations are presented in Table 2. These readings show seasonal trends, but (because they are limited to one observation of each station per month) do not show maximum or minimum temperatures.

Prevailing "offshore" (NNE and NE) winds were recorded during January, February, October and December (Table 4). The prevailing winds were "onshore" (S, SE, and SSE) during other months. High tides associated with hurricane "Hilda" occurred during the first two weeks of October. Above normal tides also occurred during April and May.

Comments: Alteration of fishery habitat by a myriad of engineering projects brought about by the expanding economy of the Galveston Bay area has become a serious problem. An evaluation of the overall effects of such projects is needed.
